

How Much Will Active/Active Cost Me?

October 2006

How much will an active/active system cost me? What will be its total cost of ownership (TCO)?

The proper calculation of TCO for a system can be a daunting task. There are, however, services available to help. One such service is VirtualADVISOR TROM from The Standish Group (<u>http://www.standishgroup.com</u>). TROM stands for Total cost of ownership Rough Order of Magnitude. It is a lot words to describe a lightweight cousin of the larger TCO assessment models, but TROM is quicker, less expensive, and less arduous to use. Basically, with TROM, Standish does all the heavy lifting and provides the client with a concise and comprehensive report that can be shared with management to make strategic and tactical decisions.

The TROM service uses a set of Standish VirtualADVISOR tools, which accept from the client a wide range of input parameters concerning the costs of the current system and the proposed system. The VirtualADVISOR tools are then used to calculate various TCO and ROI parameters.

The process begins with the VirtualADVISOR client working with a Standish STAR (STandish AdvisoR). This experienced field operative guides the client through the process of entering the required input data into a VirtualADVISOR worksheet.

VirtualADVISOR TCO Input Data

The input data covers the following costs for both the current system and the proposed system:

- hardware
- software licenses
- manpower
- hardware and software maintenance
- facilities
- software infrastructure
- database and system administration
- application maintenance
- migration
- other (trade-ins, credits, and so forth)

The input tool allows any miscellaneous category to be defined and cost factors entered for that category. Various revenue categories may also be defined and entered.

Information about the applications is also entered and includes such items as the type of application (transaction, batch, query), transaction rates, both the current and proposed systems, and the current and proposed databases.

This input data is then passed to a Standish inhouse specialist. Using a sophisticated cost and downtime database called CENTS (Comparative Economic Normalization Technology System) and other tools, the expected range of each cost element is estimated; and optimum solutions are created.

The same process is used for projects. Standish uses a process that it describes as case-based reasoning technology driven by the CHAOS database to measure and profile the input data. The CHAOS database contains over 100 pertinent attributes from over 50,000 cases submitted by over 5,000 project managers through surveys, user interviews, vendor interviews, and focus workshops.

At this point, ROI and TCO tools are used to calculate a variety of cost and return-on-investment parameters. The results include for a specified time period:

- cost of implementing and operating the system
- capitalized savings
- operational savings
- cumulative gain (savings cost)
- return on investment
- payback period

The inhouse specialist then prepares a report explaining these results and defining the best strategy to maximize ROI. The report is passed to the client's STAR, who works with the client to review the outcomes and to make recommendations for paths to pursue.

Results for Year 1 of Scenario 1 4P -	2P						[MODIFY This Y

A Page From a TROM Report

© 2006 Sombers Associates, Inc., and W. H. Highleyman www.availabilitydigest.com

The report is provided in PDF format and is organized as follows:

Introduction	The Introduction is a brief paragraph on the process and how the report was generated
Data and Assumptions	The Data and Assumptions section describes the platforms, activities, and assumptions that have gone into the making of the report. TCO, ROI, migrations, and data sources are all identified.
Project Risk	The Project Risk section provides insight into migration projects and emphasizes some of the issues that should be addressed specific to a project of this nature.
Savings	This is the TCO section. Each cost is explained, and potential savings are plotted in tabular or graphical form.
ROI	The ROI section pulls the entire document together. It provides an ROI analysis of the migration/consolidation strategy. It discusses the capitalized and operational savings. It defines the best strategy to achieve the optimum ROI.
Recommendations	Recommendations are made based on the findings of the study, and justification is provided to either continue or abandon the project.

VirtualADVISOR requires neither training nor any installation of software. The client's interface is strictly through his STAR.

The final output of the TROM service, whether it be related to a set of applications, a new project, or a migration project, will be a formal report that the client can use to determine from which alternatives he can choose based on real-life cases free of all vendor hype.

Though not related to TCO and ROI, another major part of the VirtualADVISOR service is the assessment of risk associated with implementing a project. This is supported by the extensive case study attributes found in the CHAOS database.
